## **5-YEAR REVIEW**

### **Lost River Sucker (*Deltistes luxatus*)**

#### **I. GENERAL INFORMATION**

##### **Purpose of 5-Year Reviews:**

The U.S. Fish and Wildlife Service (Service) is required by section 4(c)(2) of the Endangered Species Act (Act) to conduct a status review of each listed species at least once every 5 years. The purpose of a 5-year review is to evaluate whether or not the species' status has changed since it was listed (or since the most recent 5-year review). Based on the 5-year review, we recommend whether the species should be removed from the list of endangered and threatened species, be changed in status from endangered to threatened, or be changed in status from threatened to endangered. Our original listing of a species as endangered or threatened is based on the existence of threats attributable to one or more of the five threat factors described in section 4(a)(1) of the Act, and we must consider these same five factors in any subsequent consideration of reclassification or delisting of a species. In the 5-year review, we consider the best available scientific and commercial data on the species, and focus on new information available since the species was listed or last reviewed. If we recommend a change in listing status based on the results of the 5-year review, we must propose to do so through a separate rule-making process defined in the Act that includes public review and comment.

##### **Species Overview:**

The Lost River sucker (*Deltistes luxatus*) is a fish of the Catostomidae family. This species is endemic to the upper Klamath River basin, including the Lower Klamath Lake and Lost River sub-basins, and inhabit a small number of natural lakes and reservoirs within these basins. Mature individuals of this species are relatively large (up to 80 centimeters or 2.6 feet) and for the majority of the year individuals are only found within the lakes and reservoirs. During the spring, adults migrate up tributaries of the lakes and reservoirs to spawn in small groups over the gravel substrate of rivers and streams. However, approximately 30 percent of the spawning adults in Upper Klamath Lake spawn at gravel areas associated with groundwater-fed seeps or springs along the eastern shoreline instead of migrating up tributaries. After hatching, larvae immediately float downstream into the lake habitat to mature. Sexual maturation occurs within four to nine years, and adults will live on average approximately 12.5 years after reaching adulthood typically attempting to reproduce each year. Lost River sucker predominantly feed on zooplankton and macroinvertebrates.

##### **Methodology Used to Complete This Review:**

This review was prepared by the Klamath Falls Fish and Wildlife Office staff, following Region 8 guidance. The *Revised Recovery Plan for the Lost River sucker (Deltistes luxatus) and Shortnose sucker (Chasmistes brevirostris)* (Revised Recovery Plan; USFWS 2013), published reports, and personal communications with experts who have been monitoring various localities of this species were the primary sources of information used to update the species' status and threats. This 5-year review contains up to date information on the species' biology and threats,

and an assessment of this information compared to the 2007 5-year review. We focus on current threats to the species that are attributable to the Act's five listing factors. This review synthesizes all this information to evaluate the listing status of the species and provide an indication of its progress towards recovery. Finally, based on this synthesis and the threats identified in the five-factor analysis, we recommend a prioritized list of conservation actions to be completed or initiated within the next 5 years.

#### **Contact Information:**

**Lead Regional Office:** Larry Rabin, Deputy Division Chief for Listing, Recovery, and Environmental Contaminants, Lisa Ellis, Fish and Wildlife Biologist, Region 8, California and Nevada; (916) 414-6464.

**Lead Field Office:** Josh Rasmussen, Fish Biologist, Klamath Falls Fish and Wildlife Office, Klamath Falls, Oregon; (541) 885-2509.

#### **Federal Register (FR) Notice Citation Announcing Initiation of This Review:**

A notice announcing initiation of the 5-year review of this taxon and the opening of a 60-day period to solicit information from the public was published in the Federal Register on May 25, 2011 (76 FR 30377). We received information from six individuals or groups in response to this request.

#### **Listing History:**

##### **Original Listing**

**FR Notice:** 53 FR 27130

**Date of Final Listing Rule:** July 18, 1988

**Entity Listed:** Lost River sucker (*Deltistes luxatus*), a fish species

**Classification:** Endangered

##### **State Listing**

Lost River sucker (*Deltistes luxatus*) was listed as State Endangered by the State of California January 10, 1974.

Lost River sucker (*Deltistes luxatus*) was listed as Endangered by the State of Oregon in 1991.

#### **Associated Rulemakings:**

Critical habitat was proposed in 1994 (59 FR 61744), but not finalized. Critical habitat was again proposed in 2011 (76 FR 76337), and was finalized on December 11, 2012 (77 FR 73740).

## **Review History:**

A 5-year review of Lost River sucker status was completed in 2007 and announced in the Federal Register (73 FR 11945). The listing rule and the 2007 5-year status review are the only formalized reviews of the status that contains a five-factor analysis and conclusions.

## **Species' Recovery Priority Number at Start of 5-Year Review:**

The recovery priority number for *Deltistes luxatus* is 4C according to the Service's 2011 Recovery Data Call. This number is based on a ranking system where 1 is the highest-ranked recovery priority and 18 is the lowest (Endangered and Threatened Species Listing and Recovery Priority Guidelines, 48 FR 43098, September 21, 1983). The number 4 indicates that the taxon is a monotypic genus that faces a high degree of threat of extinction and a low recovery potential. The "C" indicates conflict with construction or other development projects or other forms of economic activity.

## **Recovery Plan**

**Name of Plan:** Revised Recovery Plan for the Lost River (*Deltistes luxatus*) and Shortnose Sucker (*Chasmistes brevirostris*).

**Date Issued:** A recovery plan for the Lost River sucker and the Shortnose sucker was finalized on March 17, 1993 (USFWS 1993). A draft revision of this plan was released October 18, 2011 (76 FR 64372), and the final plan was released April 16, 2013 (78 FR 22556).

## **II. REVIEW ANALYSIS**

### **Application of the 1996 Distinct Population Segment (DPS) Policy**

The Endangered Species Act defines "species" as including any subspecies of fish or wildlife or plants, and any distinct population segment (DPS) of any species of vertebrate wildlife. This definition of species under the Act limits listing as distinct population segments to species of vertebrate fish or wildlife. The 1996 Policy Regarding the Recognition of Distinct Vertebrate Population Segments under the Endangered Species act (61 FR 4722, February 7, 1996) clarifies the interpretation of the phrase "distinct population segment" for the purposes of listing, delisting, and reclassifying species under the Act. Lost River suckers are not listed as a DPS, and there is no new information regarding the application of the DPS policy to this species.

## **Information on the Species and its Status**

### Biology and Life History

Lost River suckers exhibit many adaptations characteristic of long-lived species. Juveniles grow rapidly until reaching sexual maturity sometime between four and nine years (Revised Recovery Plan; Perkins et al. 2000b). Adults tend to have high survival rates enabling populations to outlive unfavorable periods, such as droughts. Once Lost River suckers achieve adulthood, they are documented to live on average 12.5 years (D. Hewitt, U.S. Geological Survey, pers. comm.,

2011). Thus, for those individuals surviving to adulthood, we expect an average total life span of approximately 20 - 25 years, based on the average time to maturity and average adult life spans, with maximum ages recorded of up to 57 years (Scoppettone 1988, Buettner and Scoppettone 1990, 1991, Terwilliger et al. 2010).

Currently, the best available information indicates that the age distribution of adults in some populations is primarily comprised of older individuals because juveniles are not surviving to maturity. This is especially apparent in Upper Klamath Lake where the average length of spawning adults (a surrogate for age) of this species has been progressively increasing since 1999 (Hewitt et al. 2011, Hewitt et al. 2012). This pattern of age distribution also appears to be occurring with Lost River sucker in Clear Lake Reservoir. For example, in 2007, approximately 35 percent of all individuals captured in Clear Lake Reservoir were less than 400 mm, a size indicative of relatively young adults, indicating that recruitment to the adult population was occurring or about to occur. However, as of 2011, only 25 percent of this group was still being detected in the spawning runs suggesting mortality rates for this young adult group of nearly 75 percent. For this species, annual adult mortality rates greater than 15 – 20 percent can significantly decrease population stability and viability. The data now indicate that the adult population continues to age with few new individuals surviving to reproductive age to offset natural mortality. This type of long-term monitoring data is unavailable for all populations other than Clear Lake Reservoir and Upper Klamath Lake.

River spawning runs from Upper Klamath Lake begin when river temperatures reach 10° C (50° F), typically mid-April. Approximately 30 percent of the Upper Klamath Lake population spawns at shallow springs along the eastern shoreline of the lake beginning in early March. Both groups spawn well into May. It appears that greater than 95 percent of adults spawn every year based on long term monitoring conducted by the U.S. Geological Survey (E. Janney, U.S. Geological Survey, pers. comm., 2011). Females are highly fecund, producing 44,000 to 236,000 eggs per female per year, of which only a very small percentage survive to become juveniles (National Research Council 2004). Females broadcast their unfertilized eggs typically in the company of two males (Andreasen 1975, Buettner and Scoppettone 1990), males fertilize the eggs, and then the fertilized eggs settle within the top few inches of the substrate. Eggs are deposited in gravel substrates in areas with water depths typically less than 1.3 meters (4.3 feet) (Buettner and Scoppettone 1990). Hatching occurs around one week later.

Approximately 10 days after hatching, larvae emerge out of the gravel (Coleman et al. 1988, Buettner and Scoppettone 1990). Larvae spawned in streams quickly drift downstream into lake habitat beginning in April through July. Downstream movement mostly occurs at night near the water surface (Klamath Tribes 1996, Tyler et al. 2004, Ellsworth et al. 2010). Lost River sucker larvae tend to be encountered in open water habitat (Burdick and Brown 2010). Larvae transform into juveniles by mid-July at about 25 millimeters (1 inch) total length, and progressively move into deeper water habitats. Larvae and small juveniles appear to consume predominantly surface-oriented objects (adult midges [flies] and pollen), but a shift to benthic (bottom of the lake) objects such as midge pupae and chydorids (Cladocera; freshwater crustaceans) occurs by the time the juveniles reach 30 mm standard length (Markle and Clauson 2006).

Adult Lost River suckers inhabit lake environments with water depths of 1 to 4.5 meters (3.2 to 14.7 feet), but appear to prefer depths from 1.5 to 3.4 meters (4.9 to 11.1 feet) (Peck 2000, Reiser et al. 2001, Banish et al. 2009). Adults can become densely congregated, such as during the summer to exploit areas with suitable water quality, or they may also be relatively uniformly distributed throughout portions of the lake in which they reside (Peck 2000, Banish et al. 2009). Congregations also form in the spring prior to moving into tributaries or shoreline areas for spawning (Janney et al. 2009).

Historically, the Lost River sucker occurred with several fish species: shortnose sucker (*Chasmistes brevirostris*), Klamath largescale sucker (*Catostomus snyderi*), lamprey (*Lampetra* species), sculpin (*Cottus* species), chubs (*Gila* species), and several salmonids, including Klamath redband trout (*Oncorhynchus mykiss* sub-species), steelhead (*O. mykiss*), bull trout (*Salvelinus confluentus*), and Chinook salmon (*Oncorhynchus tshawytscha*; Hamilton et al. 2005). Many of these potentially interact with the species as predators or competitors. In addition, approximately 20 fish species have been accidentally or deliberately introduced into the range of these species, and a few of these now comprise a significant portion of the fish community, including fathead minnow (*Pimephales promelas*) and yellow perch (*Perca flavescens*) (Scoppettone and Vinyard 1991, National Research Council 2004). Several avian predators also occur in the system including bald eagles (*Haliaeetus leucocephalus*), American white pelicans (*Pelecanus erythrorhynchus*), and double-crested cormorants (*Phalacrocorax auritus*), as well as other species, such as grebes, terns, and mergansers, that take smaller fish. Likewise, a number of pathogens or parasites have been identified from moribund suckers, including anchor worm (*Lernaea* species; a parasitic copepod), *Trichodina* species (an external ciliate protozoan), and the bacterium *Flavobacterium columnare* (Holt 1997, Foott 2004, Foott et al. 2010).

### Spatial Distribution

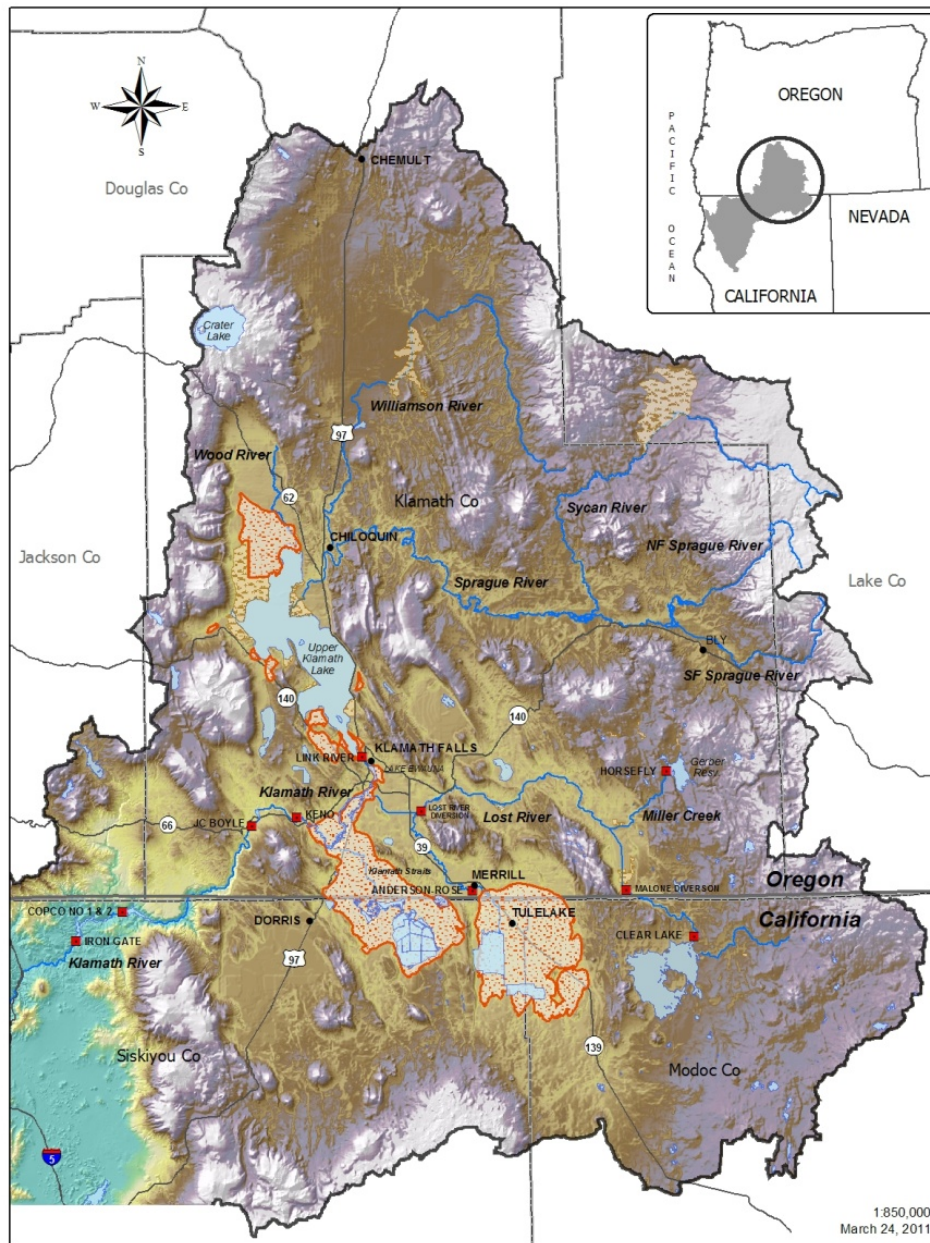

The Lost River sucker is endemic to the upper Klamath River basin, including the Lost River and Lower Klamath Lake sub-basins (Figure 1). It is difficult to know precisely which tributaries and bodies of water this species historically occupied because records are sparse, but Lost River sucker occurred in Upper Klamath Lake, Lower Klamath Lake, Tule Lake, and Clear Lake Reservoir as well as the major tributaries to these water bodies including the Sprague River, Wood River, Lost River, Willow Creek, and the Klamath River above Lower Klamath Lake. Prior to listing, significant amounts of suitable habitat were lost or modified due to conversion of wetlands to agricultural uses and development which restricted its distribution. For example, approximately 150,700 acres (61,000 hectares) of habitat were lost by lowering Tule and Lower Klamath Lakes (National Research Council 2004). In addition, several migration barriers were constructed throughout the range of the species, including the Link River Dam (1921), Clear Lake Dam (1910), Wilson Diversion Dam (1912), Malone Diversion Dam (1921), Anderson-Rose Dam (1921), Chiloquin Dam (1914), and the railroad (1909), as well as many smaller structures (BOR 2000).

At the time of listing, the Lost River sucker occurred in Upper Klamath Lake and Clear Lake Reservoir (Klamath Co., Oregon and Modoc Co., California, respectively) (USFWS 1988a). Populations in J.C. Boyle Reservoir (Klamath Co., Oregon), Iron Gate Reservoir, Copco

Reservoir, Sheepy Lake, Lower Klamath Lake, and Tule Lake (all in Siskiyou Co., California) were believed to be very small or extirpated. The overall distribution has not changed substantially since listing and the last status review (2007), but some additional information since the last 5-year status review indicates that a resident population of Lost River suckers may exist in the Sprague River near Beatty, OR (M. Buettner, U.S. Fish and Wildlife Service, pers. comm. 2009). Spawning was known to occur at this area, but detection of adults-sized individuals during the summer indicates that occupation occurs outside of the spawning period, a fact which was previously unknown. The information concerning this is still relatively limited, and so more in-depth observations are required to better understand the permanency, size, and uniqueness of this group of individuals.

During the spawning season, approximately 70 percent of Lost River sucker adults from Upper Klamath Lake utilize the lower Williamson and Sprague Rivers (Buettner and Scoppettone 1990, Tyler et al. 2004, Ellsworth et al. 2007); the remainder spawn at springs along the margins of Upper Klamath Lake (Buettner and Scoppettone 1990, National Research Council 2004). Mark-recapture data indicate that the two stocks maintain a high degree of fidelity to spawning areas and seldom interbreed (Hayes et al. 2002, Barry et al. 2007), although the lack of genetic distinction suggests that some mixing may occur (Dowling 2005). The Willow Creek drainage is the only known spawning habitat for Lost River sucker in Clear Lake Reservoir. Throughout their range, many spawning sub-populations have been extirpated because of barriers and other habitat alterations; these include Harriman Springs, Barkley Springs, and Tecumseh Springs within the Upper Klamath Lake system, and areas along the Lost River near Olene and Big Springs near Bonanza (Bendire 1889, Howe 1969).

Two major improvements in habitat connectivity and availability have occurred since the 2007 five year review for this species. The first major improvement to habitat connectivity was the removal of the Chiloquin Dam in 2008, which particularly benefits migrating adults and larvae during the spawning period. Previous to removal of this dam, the approximately 120 kilometers (75 miles) of potential spawning habitat and migration corridor within the Sprague River could only be accessed by migrating adults by means of an impaired fish ladder. The second major improvement was the restoration of the freshwater marsh where the Williamson River entered Upper Klamath Lake, known as the Williamson River delta. Approximately 2,500 hectares (6,000 acres) of potential rearing habitat for larvae and juveniles were reconnected to the lake and river when levees were breached in 2008 and 2009.

**Figure 1** The upper Klamath River Basin. Orange shaded areas indicate portions of lost or altered aquatic habitat, including wetland habitat, in the upper Klamath River Basin that formerly provided habitat for the sucker. Red squares mark the locations of major dams, many of which impede sucker passage.

## Abundance

At the time of listing, the Lost River Sucker population in Upper Klamath Lake was estimated to be approximately 11,000 to 23,000 individuals (53 FR 27130). This early estimate was probably inaccurate, because statistical assumptions necessary for modeling population size were likely not met. Nevertheless, after review of available data, a special committee of the

National Research Council concluded that: “For purposes of [Endangered Species Act] actions, the critical facts, which are known with a high degree of certainty, are that the fish are much less abundant than they originally were and that they are not showing an increase in overall abundance” (National Research Council 2004:203).

Because of the generally dispersed distribution of Lost River sucker and extensive habitat, accurate estimates of population size are extremely difficult to obtain. Additionally, most populations have not been monitored sufficiently to produce adequate data to even attempt a reasonable estimate of population size. In 2011, Upper Klamath Lake monitoring detected or captured approximately 25,000 tagged Lost River suckers participating in the annual spawning congregations and runs (Brian Hayes, USGS, pers. comm. 2011). Estimates of what proportion of the total population is tagged are unavailable, but these data suggest that Lost River sucker number between 50,000 and 100,000 in Upper Klamath Lake.

Long-term monitoring of Lost River sucker spawning populations in Upper Klamath Lake has revealed several trends in abundance and demography, including consistent annual declines in the number of individuals participating in the runs and an increasing trend in the average size (and therefore age) of spawning adults. Since the year 2002, Lost River sucker spawning congregations in Upper Klamath Lake have declined by approximately 45 percent across both the shoreline spring-spawning (Figure 2) and the river-spawning subpopulations (Hewitt et al. 2011, Hewitt et al. 2012). Although this data extends back to 2002, this analysis was unavailable for the 2007 5-year status review (see USFWS 2011 Appendix II for a discussion of this analysis). Over this same period, the Upper Klamath Lake river-spawning populations have exhibited an increasing trend in length (approximately 8 mm increase in median length annually [Figure 3]; Janney and Shively 2007, Janney et al. 2008, Hewitt et al. 2011, Hewitt et al. 2012) presumably because recruitment to the adult population is minimal and the monitoring is tracking the same individuals year after year as they age.

Data on other populations are extremely limited, but the minimal monitoring efforts completed for these populations imply very low numbers of individuals (Desjardins and Markle 2000, Shively et al. 2000b, Hodge and Buettner 2009b). Although, mark-recapture monitoring has occurred on the Clear Lake Reservoir population for several years (Barry et al. 2007), capture rates of Lost River suckers overall are low. Slightly less than 500 tagged Lost River suckers were detected during the 2011 spawning run up Willow Creek from Clear Lake Reservoir. In 2007, approximately 35 percent of all individuals captured in Clear Lake Reservoir were less than 400 mm, a size indicative of relatively young adults, indicating that recruitment to the adult population was occurring or about to occur. However, as of 2011, only 25 percent of this group was still being detected in the spawning runs suggesting mortality rates for this young adult group of nearly 75 percent. For this species, annual adult mortality rates greater than 15 – 20 percent can significantly decrease population stability and viability. The data now indicate that the adult population continues to age with few new individuals surviving to reproductive age to offset natural mortality.

At the time of listing, the Lost River sucker was believed to have been extirpated from Tule Lake. However, during a three-year monitoring effort (2006 – 2008) approximately 400 individual Lost River suckers were captured here (Hodge and Buettner 2009b). Historical Tule Lake has been reduced to two irrigation sumps, in other words collection areas from drained

water, which are connected by a canal and gates to manage water between them which restricted movement (Figure 1). In the 2006 – 2008 monitoring, Lost River suckers were only found in sump 1A (the northernmost of the two wetted sumps). Recent translocation experiments by the Service documented that Lost River suckers transported from sump 1A to 1B survived several months in sump 1B, but returned immediately to sump 1A when access was provided through the gates (U.S. Fish and Wildlife Service, unpublished data, 2012). It is unknown why sump 1A is preferred by Lost River suckers over sump 1B.

Although the source of the Lost River suckers in Tule Lake has not been thoroughly investigated, it is likely that larval fish disperse from Upper Klamath Lake and Clear Lake Reservoir through the irrigation canals to Tule Lake which serves as a terminal sump for the Klamath Irrigation Project. The fact that suckers are found throughout the canal system of the Klamath Irrigation Project supports this assumption. When the irrigation canals are drained at the end of the irrigation season each fall, the Bureau of Reclamation salvages suckers from these canals and places them in sump 1A of Tule Lake thus supplementing the population there (Kyger and Wilkens 2011). Although a very low level of spawning by Lost River suckers from sump 1A of Tule Lake has been documented in the Lost River downstream of Anderson Rose Dam, spawning success seems limited due to lack of suitable spawning habitat, and at this time there is no evidence that the spawning that occurs there produces offspring (Hodge and Buettner 2009a). Nevertheless, the Tule Lake sump 1A population of Lost River suckers is an important auxiliary to Clear Lake Reservoir within the Lost River subbasin. The National Research Council concluded that “[f]rom the water quality perspective, it appears that the Tule Lake population is potentially closer to survival conditions than the Upper Klamath Lake population” (National Research Council 2004:134). That is, water quality in Tule Lake may not be adversely related to the survival of Lost River suckers to the same degree as it is in Upper Klamath Lake.

A similar effort to assess the population in Keno Reservoir (2008–2011) detected approximately 200 individual Lost River suckers (Kyger and Wilkens 2010). In 1999, sampling at 36 sites within the Lost River produced only a single Lost River sucker (Shively et al. 2000b). Similarly, sampling within the reservoirs on the Klamath River downstream of Keno yielded only three adult Lost River suckers between 1997 and 1999 (Desjardins and Markle 2000).

Figure 2 The percentage of Lost River sucker in the annual spawning run at the springs along the eastern shoreline of Upper Klamath Lake as compared to the number that was present in 2002 (Hewitt et al. 2012; page 28).

Figure 3 Boxplots of fork lengths of male (*top*) and female (*bottom*) Lost River suckers captured at pre-spawn staging areas in Upper Klamath Lake and in the Williamson and Sprague Rivers, 2000–2009. Dots in the boxes represent the medians and the boxes cover the central 75 percent of the data. The number of fish included in the boxplots for each year is given near the x-axis in each panel. The blue lines are simple linear regressions through the medians and the slope of the regression for each sex is reported as an average annual growth rate. Taken from Hewitt et al. (2012).

### Habitat or Ecosystem

Lost River suckers use a variety of aquatic habitats through their lives including lakes and reservoirs (Table 1), and rivers. Out-migrating larvae (those larvae that have hatched and

begun to drift downstream), as well as spawn-ready adults, utilize river and stream habitat as a migration corridor, but specific habitat requirements during these migrations are unknown. In the lakes and reservoirs, larvae generally inhabit relatively shallow areas often associated with emergent vegetation (Klamath Tribes 1996, Cooperman 2004, Crandall 2004). (The term "emergent vegetation" refers to plants that are rooted in soil underwater, but with tops extending above the water. Cattails and bulrushes are common examples in this area.) In some locations, such as in Clear Lake Reservoir, emergent vegetation is lacking, but larvae still inhabit relatively shallow areas. It appears that submerged vegetation (rooted vegetation where the tops don't reach the water surface) is relatively unimportant as a structural habitat component for larvae, largely because it is not generally available early in the summer when larvae are present (Cooperman 2004).

As Lost River suckers mature they tend to utilize deeper habitats within the lakes and reservoirs they inhabit. Juvenile (or young of the year) Lost River suckers begin to use deeper water as the season progresses (less than about 1.2 meters [ 3.9 feet]), including vegetated and un-vegetated shoreline habitat (Moyle 2002), although these areas are still relatively shallow. Adults and sub-adults use water depths between 1 to 4.5 meters (3.3 to 14.7 feet), but appear to prefer depths of 1.5 to 3.4 meters (4.9 to 11.2 feet) (NRC Reiser et al. 2001, 2004).

Adults are widely distributed in Upper Klamath Lake during fall and winter, but will congregate in the spring prior to moving into tributaries or shoreline areas with springs to spawn. Adults are generally restricted to the northern half of Upper Klamath Lake during the summer, at times becoming very congregated in spring dominated areas (specifically Pelican Bay) during periods of unsuitable water quality (Banish et al. 2009). In Clear Lake Reservoir, adult Lost River suckers utilize the western lobe of the reservoir during winter, but are generally dispersed throughout both the east and west lobes the rest of the year (D. Hewitt, U.S. Geological Survey, pers. comm., 2011), except for the brief period when they run up Willow Creek to spawn.

Little is known about the long-term water quality dynamics of much of the range of this species, but sufficient data do exist for Upper Klamath Lake and Keno Reservoir. Water quality conditions in Upper Klamath Lake are driven by high nutrient loads. The lake was highly productive or eutrophic prior to settlement by Europeans in the mid-19<sup>th</sup> century, but it has become hypereutrophic (characterized by an over-abundant accumulation of nutrients that support a dense growth of algae and other organisms) from loading attributed to a combination of external (pumping of diked wetlands, farm/ranch run-off, and roads) and internal (lake sediments) sources (Snyder and Morace 1997, Boyd et al. 2002, Independent Multidisciplinary Science Team IMST 2003, Bradbury et al. 2004, Eilers et al. 2004, National Research Council 2004, Graham et al. 2005). Eilers et al. (2004) concluded that the lake sediments of Upper Klamath Lake were enriched with nutrients at higher rates than the historical norms because of anthropogenic land management practices during the early 1900's.

These very high nutrient loads stimulate excessive algal productivity, especially of a particular species of blue-green algae or cyanobacteria (*Aphanizomenon flos-aquae*; AFA) that dominates during most of the growing season. During the algal bloom dissolved oxygen levels can be extremely high during the day as the algae photosynthesizes and extremely low at night as the

algae respire. Chronically low levels of dissolved oxygen that are detrimental or even fatal to most fish, including suckers, can also occur (Morace 2007). In years when the bloom crashes, the subsequent decomposition of the algae by bacteria can significantly deplete oxygen from the surrounding water. Concentrations of the toxic form of ammonia (un-ionized ammonia;  $\text{NH}_3$ ) may also reach levels detrimental to Lost River sucker as nitrogenous compounds are produced during decomposition of the algae and altered by the pH of the water (Perkins et al. 2000a, Boyd et al. 2002, IMST 2003, National Research Council 2004, Wood et al. 2006, Jassby and Kann 2010). Many of these same processes occur in Keno Reservoir predominantly because Upper Klamath Lake also releases heavy organic and nutrient loads in downstream flows (Sullivan et al. 2008, Kirk et al. 2010, Sullivan and Rounds 2011). Likewise, the Sprague River, the primary spawning habitat for suckers in Upper Klamath Lake and the largest tributary to the Williamson River, is listed as water quality impaired for nutrients, temperature, sediment, and dissolved oxygen under section 303d of the Clean Water Act (Boyd et al. 2002). Lastly, another cyanobacterium species (*Microcystis aeruginosa*) within Upper Klamath Lake may produce toxins harmful to sucker liver tissue (Vanderkooi et al. 2010), but the role this toxin has on the status of Lost River sucker in Upper Klamath Lake are currently unknown.

In contrast, data on water quality are extremely sparse for all other lakes and reservoirs inhabited by populations of this species. Data collected during 1991 to 1995 near Clear Lake Dam and within the east and west lobes of the reservoir indicate that conditions are typically not at levels considered detrimental to fish. Dissolved oxygen levels rarely declined below 4 milligram/liter, and temperatures infrequently exceeded 26 degrees Celsius (79 degrees Fahrenheit; Hicks 2001).

**Table 1 Basic information on the lakes and reservoirs of the upper Klamath Basin in which Lost River sucker are found, adapted from Table 3-1 from The National Research Council of the National Academies (2004:96). One hectare is equivalent to approximately 2.47 acres, and 1 meter is equivalent to approximately 3.3 feet, and 1 kilometer is equivalent to 0.6 miles.**

	Size before 1900 (hectares)		Size since 1960 (hectares)			Mean Depth <sup>b</sup> (meters)	Associated Stream Habitat <sup>g</sup> (kilometers)

## Genetics

In a combined assessment of mitochondrial (mtDNA) and nuclear DNA, Dowling (2005) found that Lost River suckers are relatively distinct genetically (mtDNA) from the other sucker species within the Klamath River basin (shortnose sucker [*Chasmistes brevirostris*], Klamath largescale sucker [*Catostomus snyderi*], and Klamath smallscale sucker [*Catostomus rimiculus*]). Only 5 (2 percent) of the 250 Lost River sucker analyzed exhibited mtDNA typical of another sucker species. Similarly, microsatellite markers also indicate that Lost River suckers do not regularly interbreed with the other suckers species in the family Catostomidae in the basin (Tranah and May 2006). However, an incomplete survey of nuclear DNA markers did not provide discrimination from the other species (Dowling 2005). Genetic variation of mtDNA among populations of Lost River suckers suggests that populations in the Lost River subdrainage are somewhat genetically distinct from Upper Klamath Lake populations (Dowling 2005). There is no information relating to specific trends of genetic variation.

## Species-specific Research and/or Grant-supported Activities

Research benefitting or targeting this species is completed or funded by several organizations. The Bureau of Reclamation currently funds long-term monitoring of adult populations and research to better estimate the rates of entrainment of larval Lost River suckers into Klamath Project facilities through contracts with the U.S. Geological Survey and Oregon State University. Entrainment is when individuals (most often larvae and juveniles in the case of Lost River suckers) are pulled along with the force of water, which often results in fish being trapped in water management structures (see Factor E for further detail).. Entrainment may occur through natural features, such as a river corridor, or into irrigation canals or other similar structures, such as dams and hydroelectric facilities. In addition to this Bureau of Reclamation is conducting radio telemetry work to determine spawning patterns within Clear Lake Reservoir. The Bureau of Reclamation is also funding research to better understand physiological dynamics of juveniles during summer in Upper Klamath Lake through collaboration with the Service. Several organizations, including the U.S. Fish and Wildlife Service, also pursue active restoration programs within the upper Klamath River basin which often includes projects that can benefit the Lost River sucker. Other research includes clarification of the distribution and dynamics of Lost River sucker in Clear Lake Reservoir, improvement of passage within the Lost River, clarification of the effects of microcystin (a toxin that affects suckers and is described in further detail under Factor E of the Five-Factor Analysis below), and evaluation of methods for off-site rearing.

## **Five-Factor Analysis**

The following five-factor analysis describes and evaluates the threats attributable to one or more of the five listing factors outlined in section 4(a)(1) of the Act.

## **FACTOR A: Present or Threatened Destruction, Modification, or Curtailment of Habitat or Range**

Loss of habitat was a major factor leading to the listing of the Lost River sucker (53 FR 27130). Historic habitat loss was especially pronounced in the Lost River–Tule Lake and Lower Klamath subbasins, where approximately 150,000 acres (approximately 77 percent) of sucker habitat were lost when Tule Lake and Lower Klamath Lake were drained early in the 20<sup>th</sup> century (53 FR 27130; NRC 2004). These lakes functioned as catchments for larval and juvenile suckers emigrating out of Upper Klamath Lake or drifting downstream through the Lost River. Loss of these habitats has reduced the viability of the species by reducing the number of healthy, viable populations (redundancy) and drastically decreasing the numbers of Lost River sucker rangewide. Loss of these areas has restricted the species to only two populations that are able to achieve even marginal reproduction (Upper Klamath Lake and Clear Lake Reservoir). This puts the species at significant risk of catastrophic events, such as die-offs, given the lack of population redundancy that could be used to replenish affected populations. Access to important habitat areas for spawning, rearing, and other needs was also greatly curtailed. About 70 percent of the original 50,000 acres of wetlands surrounding Upper Klamath Lake were diked and drained between 1889 and 1971, leaving about 16,000 acres in 1990 connected to the lake (Snyder and Morace 1997, Aquatic Science Resources 2005). These wetlands are important as rearing habitat for larval and juvenile suckers, and the loss of access to such habitats may cause utilization of unsuitable habitats by these life stages (Aquatic Science Resources 2005).

Despite these considerable losses of important habitats, the general trend of habitat loss, modification and curtailment has stabilized or is improving (see Habitat Restoration section below). Currently, most actions that would affect aquatic habitats inhabited by Lost River sucker are regulated under various state and federal laws (see *Factor D – Inadequacy of regulatory mechanisms* for an analysis of the adequacy of regulations relative to Lost River sucker recovery), which ensure that effects of these actions on Lost River sucker are minimized during project planning and consultation. Two extremely significant improvements to the status of the species since the most recent review are the removal of the Chiloquin Dam and restoration and reconnection of the Williamson River delta.

### Adverse Water Quality

Lake suckers such as Lost River sucker are relatively tolerant of water quality conditions unfavorable for many other fishes, tolerating higher pH (more basic conditions), temperature, and un-ionized ammonia concentrations, and lower dissolved oxygen concentrations (Saiki et al. 1999). Nevertheless, many of the water bodies currently occupied by Lost River sucker periodically possess conditions that are potentially harmful or fatal to the species. Much of this is due to large amounts of dissolved nutrients which promote biological productivity, such as algal growth. Throughout the year, the dynamics of algal blooms affect dissolved oxygen levels (ranging between anoxic to supersaturated conditions), pH, and un-ionized ammonia, all of which can impact fish health and survival. These processes are particularly important in Upper Klamath Lake and Keno Reservoir.

Upper Klamath Lake was naturally highly productive or eutrophic prior to European settlement, but it has since become even more productive or “hypereutrophic” (Boyd et al. 2002, Bradbury et al. 2004, Eilers et al. 2004). Nutrients driving biological production in Upper Klamath Lake originate from external sources (such as water pumped from diked wetlands and run-off from agriculture and roads) and internal sources (namely lake sediments) (Snyder and Morace 1997, Boyd et al. 2002, IMST 2003). The accumulation of nutrient-bearing sediments in Upper Klamath Lake has dramatically increased during the 20<sup>th</sup> century, and these “modern” sediments are higher in nitrogen and phosphorus than pre-settlement sediment (Eilers et al. 2001), suggesting that even though sediments are a natural source of nutrients, the current levels are probably higher than they would have been without anthropogenic (human-generated) influences.

In conjunction with this increased nutrient loading, significant alterations to Lost River sucker habitat in Upper Klamath Lake have occurred over the last century due to changes in the algal community. Core samples of bottom sediments indicate that the cyanobacterium AFA were not present in Upper Klamath Lake prior to the 1900s (Bradbury et al. 2004, Eilers et al. 2004). It now dominates the algal community, and because of the high concentrations of nutrients available (as well as its ability to fix nitrogen), is able to reach seasonally high densities that cause degraded water quality (Boyd et al. 2002). *Aphanizomenon flos-aquae* often occur in massive blooms, constituting over 90 percent of the biomass of photosynthetic organisms in the lake during the summer (Boyd et al. 2002). High photosynthetic activity can supersaturate the water with dissolved oxygen (DO) during daylight hours, and subsequent respiration at night can deplete DO levels. Both supersaturation and depletion of DO can be detrimental to Lost River suckers.

In the Upper Klamath Lake, these cyanobacteria blooms are subject to catastrophic population crashes. The subsequent decomposition of the large quantities of organic matter causes extreme DO depletion in the water column and releases a potentially toxic by-product, ammonia, which, in turn, increases the pH of the water making the water more basic. As pH becomes more basic, the proportion of the more toxic form of ammonia (un-ionized ammonia) also increases. Furthermore, the nitrogen made available from the decay of the AFA may also temporarily spur the growth of other photosynthetic organisms, including the toxin-producing cyanobacterium *Microcystis aeruginosa*. The conditions associated with massive cyanobacteria blooms and crashes have been linked to mass fish mortality events in Upper Klamath Lake that have included adult Lost River suckers (Perkins et al. 2000a). Because all Lost River sucker life stages (larvae, juveniles, and adults) in the Upper Klamath Lake watershed are almost entirely confined to the lake during the summer when water quality is poor, the entire population in the watershed is vulnerable to alterations of the habitat due to poor water quality.

Data concerning specific water quality affecting other populations are limited. Clear Lake Reservoir appears to be less productive than Upper Klamath Lake (BOR 1994, Hicks 2001), and therefore does not experience similar blue-green algae blooms. Data collected during 1991 to 1995 in Clear Lake Reservoir indicate that dissolved oxygen levels rarely declined below 4 milligrams/liter, and temperatures rarely exceeded 26 degrees Celsius (79 degrees Fahrenheit; Hicks 2001), levels that would be considered detrimental to Lost River suckers. Conversely, Keno Reservoir, downstream of Upper Klamath Lake, frequently and persistently experiences extremely

poor water quality conditions (Sullivan et al. 2008, Kirk et al. 2010). Dissolved oxygen levels of less than 1 milligram/liter, well below levels typically considered detrimental to fish, occur regularly (Kirk et al. 2010). This is due, in large degree, to the considerable amounts of organic materials passing from Upper Klamath Lake to Keno Reservoir through the Link River. *Aphanizomenon flos-aquae* is relatively sensitive to jostling, and this downstream trip frequently kills the colonies which then begin the decomposition cycle mentioned above. In addition, the water passing from Upper Klamath Lake is relatively high in available nutrients that stimulate biological productivity. The Sprague River, the primary spawning habitat for suckers in Upper Klamath Lake, is listed as water quality impaired for nutrients, temperature, sediment, and dissolved oxygen under the section 303d of the Clean Water Act (Boyd et al. 2002). The Lost River and Klamath River downstream of Keno Reservoir have been listed as impaired for DO, ammonia toxicity, chlorophyll-a (a specific form of chlorophyll used in photosynthesis that is used to characterize bloom dynamics of AFA), and temperature related to a variety of identified pollutants and habitat modifications (Kirk et al. 2010).

In summary, adverse water quality is a critical threat to Lost River sucker, and substantial improvement is not expected in the near future. It is reasonable to expect that mortality events caused by poor water quality that will significantly affect sucker populations will continue to periodically occur in Upper Klamath Lake. Given the reduced numbers of individuals and populations of this species, these poor water quality events may represent a significant threat to the species.

#### Habitat Degradation

Approximately 400 habitat restoration projects have been recently completed or are being planned in the Upper Klamath Lake basin. Because such efforts are relatively recent, population-level responses by Lost River sucker are not yet apparent. The foremost project that has occurred since the previous 5-year Status Review of this species is the restoration of the delta where the Williamson River enters Upper Klamath Lake. Lost River sucker have been documented utilizing portions of the approximately 6,000 acres of potential larvae and juvenile rearing habitat that were restored in 2007 and 2008 (Erdman et al. 2011). Although more time will be needed for the area to recover to its previous natural state due to the subsidence from agricultural use, this is still a major advancement toward the recovery of Lost River sucker. Another significant recovery action that occurred in the past five years was the removal of Chiloquin Dam on the Sprague River in 2008. The dam was identified in the 1988 listing as a threat to the Lost River sucker because it blocked access to upstream spawning areas (53 FR 27130). Removal effectively unblocks approximately 120 kilometers (75 miles) of the Sprague River for spawning and migration of adults and larvae. Insufficient time has passed to completely assess the overall effects on the population, but it is believed that this extremely important actions, in conjunction with the many other restoration activities, will result in improved status of the species.

#### Summary of Factor A

The threats discussed under Factor A continue to pose the greatest risk to the Lost River sucker. Restoration of the Williamson River Delta and removal of the Chiloquin Dam are important

milestones towards the recovery of the species, and numerous smaller restoration activities provide incremental improvement towards recovery. Nevertheless, substantial loss and alteration of aquatic habitat, including unsuitable water quality throughout the range of the Lost River sucker, continue to threaten to the existence of the species.

#### **FACTOR B: Overutilization for Commercial, Recreational, Scientific, or Educational Purposes**

Overutilization contributed to declining population levels prior to listing (53 FR 27130), but recreational harvest has been prohibited since 1987. Regulated take of Lost River sucker for scientific purposes under section 10 of the Act is authorized for 10 individuals or organizations, including federal, state, tribal, academic and private entities, and although not considered a current threat to population status, the demographic effects of these collections need to be regularly evaluated. The purpose of this research is to support recovery by providing information for the recovery plan and reviews of the species' status. There is no evidence that overutilization is currently a threat to the species.

#### **FACTOR C: Disease or Predation**

Non-native fishes were identified as a potential threat at the time of listing through predation or as sources of exotic diseases/parasites, although no direct evidence was cited. Since then, controlled experiments have demonstrated that adult fathead minnows prey on sucker larvae (Markle and Dunsmoor 2007). In Upper Klamath Lake, higher fathead minnow abundance was negatively associated with Lost River sucker survival rates (Markle and Dunsmoor 2007). These data suggest that predation by highly-abundant fathead minnows may be an important threat to larval sucker survival, which may be exacerbated by the loss of emergent wetland habitat that provides cover for the Lost River sucker larvae. Other non-native fishes may also pose a threat to Lost River sucker; however, little quantitative information exists to indicate their influence on sucker abundance and distribution.

Although not mentioned at the time of listing as a threat, several species of birds may prey on Lost River sucker, but the ultimate effect to the status of the species from these avian predators is currently unknown. Bald eagles have been observed perching in trees directly above Ouxy Springs, which is one of five areas where Lost River sucker spawn along the eastern shoreline of Upper Klamath Lake. In Clear Lake Reservoir, radio-tags and Passive Integrated Transponders (PIT tags, used for tracking) of individual Lost River sucker have been located on islands associated with nesting colonies of American white pelican, double-crested cormorant, and great blue heron (*Ardea herodias*) (U.S. Geological Survey Klamath Falls Field Station, unpublished data). Adult Lost River suckers are susceptible to avian predation during the spawning run when they are congregated within a small area (such as Willow Creek, the main spawning tributary to Clear Lake Reservoir) and occur in shallower water relative to larger bodies of water. Such predation on spawning adults may increase mortality rates of this crucial life stage, but it may also cause altered behavior during this critical period. For example, predation on adults at spawning sites may limit the amount of time spent on the spawning ground. Throughout the range of the species there are also numerous species of piscivorous birds, including terns, grebes, and mergansers, that can target juvenile and larvae Lost River sucker.

Parasites were also not identified as a threat at the time of listing, but information suggests they could be a threat to the suckers. Anchor worm parasitism on age-0 Lost River suckers appears to be highly variable from year to year in Upper Klamath Lake (ISRP 2005, Bottcher and Burdick 2010). From 1994-1996, the percent of age-0 suckers (all species) parasitized by anchor worms ranged from 0 percent to 7 percent, but during 1997 through 2000 it increased to between 9 and 40 percent. The term age-0 sucker refers to individuals that have lived less than one year, but is most often used in reference to juveniles. In 2008 only four percent of captured juvenile suckers were infected with external parasites, but this jumped to 18 percent in 2009 (Bottcher and Burdick 2010). Parasites can lead to direct mortality, provide a route for pathogens to enter fish (since they create a wound), or can make fish more susceptible to predation (Robinson et al. 1998). We currently do not have enough information to accurately assess the degree to which parasites negatively impact Lost River sucker survival and productivity.

### Blue-green Algal Toxins

The potential impacts of the blue-green algal or cyanobacteria toxins Microcystin have recently come to light. Microcystin is a toxin produced by *Microcystis aeruginosa* that primarily affects the liver causing a variety symptoms, but it can also affect the intestines, kidneys, heart, spleen, and gills (Malbrouck and Kestemont 2006). In a 2007 survey, 49 percent of a sample of juvenile suckers (all species) from Upper Klamath Lake (n = 47) collected at 11 shoreline sites exhibited indications of microcystin exposure (Vanderkooi et al. 2010). One hypothesis is that the toxin is secondarily ingested when suckers consume midge larvae (Chironomidae), which feed on the algae (Vanderkooi et al. 2010). Further investigations are required to better understand the degree to which these toxins threaten the Lost River sucker within Upper Klamath Lake.

In summary, there has been no apparent reduction in the magnitude of the threats to the species from disease or predation since the time of listing. Notwithstanding the uncertainty associated with the specific impacts of predation and disease to Lost River sucker it is probable that these factors continue to pose a threat to the species. These threats of predation and disease may directly cause mortality, indirectly promote higher mortality rates, or potentially alter behavior during critical periods. More research concerning these factors is required to better understand their role as threats to Lost River sucker.

## **FACTOR D: Inadequacy of Existing Regulatory Mechanisms**

In the listing rule for Lost River sucker, the analysis of regulatory mechanisms that could protect the species was limited to state (Oregon and California) Endangered Species Acts or provisions, but there are additional State and Federal laws and regulations in place that are pertinent to federally listed species, each of which may contribute in varying degrees to the conservation of the Lost River sucker.

### Federal Regulations

The Endangered Species Act is the primary Federal law providing protection for this species. The Service's responsibilities include administering the Act, including sections 7, 9, and 10 that

address take. Section 3(18) defines “take” to mean “to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct.” Service regulations (50 CFR 17.3) define “harm” to include significant habitat modification or degradation which actually kills or injures wildlife by significantly impairing essential behavioral patterns, such as breeding, feeding or sheltering. Harassment is defined by the Service as an intentional or negligent action that creates the likelihood of injury to wildlife by annoying it to such an extent as to significantly disrupt normal behavioral patterns which include, but are not limited to, breeding, feeding, or sheltering. The Act provides for civil and criminal penalties for the unlawful taking of listed species. Incidental take refers to the taking of listed species as part of an otherwise lawful activity by a Federal agency or applicant (50 CFR 402.02). Section 7 consultations under the Act consider if the proposed action may adversely affect the species and may include reasonable and prudent measures for reducing impacts. Since listing of the Lost River sucker, the Service has analyzed the potential effects of Federal projects under section 7(a)(2), which requires Federal agencies to consult with the Service prior to authorizing, funding, or carrying out activities that may affect listed species. In May 2013, we issued a Biological Opinion addressing the effects of the Klamath Project, operated by the U.S. Department of Interior Bureau of Reclamation, on the Lost River sucker (NMFS and USFWS 2013). At that time we concluded that “the continued operation of the [Klamath] Project for a 10-year term is not likely to jeopardize the continued existence of LRS [Lost River sucker] and SNS [shortnose sucker] or result in the destruction or adverse modification of their critical habitat” (NMFS and USFWS 2013:196). Biological opinions, the result of consultation under section 7 between the Service and another Federal agency, may exempt incidental take from the prohibitions of section 9, and may include reasonable and prudent measures that minimize the amount or extent of incidental take of listed species associated with a project. Section 9 prohibits the taking of any federally listed endangered or threatened species. For projects without a Federal nexus that would likely result in incidental take of listed species, the Service may issue incidental take permits to non-Federal applicants pursuant to section 10(a)(1)(B). To qualify for an incidental take permit, applicants must develop, fund, and implement a Service-approved Habitat Conservation Plan (HCP) that details measures to minimize and mitigate the project’s adverse impacts to this species.

Under section 404 of the Clean Water Act, the U.S. Army Corps of Engineers (Corps or USACE) regulates the discharge of fill material into waters of the United States, which include navigable and isolated waters, headwaters, and adjacent wetlands (33 U.S.C. 1344). In general, the term “wetland” refers to areas meeting the Corps’ criteria of hydric soils, hydrology (either sufficient annual flooding or water on the soil surface), and hydrophytic vegetation (plants specifically adapted for growing in wetlands). Any action with the potential to impact waters of the United States must be reviewed under the Clean Water Act, which would include consultation under section 7 of the Act if the action may affect a listed species or designated critical habitat. The Clean Water Act (33 U.S.C. 1251) also regulates the discharge of pollutants into waters of the United States and sets water quality standards for all contaminants in surface waters. Section 303(d) of the Clean Water Act requires that states identify water-bodies that do not meet those standards and develop water quality management plans to achieve standards and protect beneficial uses. As part of this process, Total Maximum Daily Loads have been developed for much of the range of the Lost River sucker, including the Upper Klamath Lake drainage (Boyd et al. 2002) and the Upper Klamath and Lost River subbasins (Kirk et al. 2010).

In addition, the National Environmental Policy Act (NEPA; 42 U.S.C. 4371 *et seq.*) provides some protection for listed species that may be affected by activities undertaken, authorized, or funded by Federal agencies. Prior to implementation of projects with a Federal nexus, NEPA requires the agency to analyze the project for potential impacts to the human environment, including natural resources. In cases where that analysis reveals significant environmental effects, the Federal agency must propose mitigation alternatives that would offset those effects (40 C.F.R. 1502.16). These mitigations usually provide some protection for listed species. However, NEPA does not require that adverse impacts be fully mitigated, only that impacts be assessed and the analysis disclosed to the public.

### State Regulations

The Lost River sucker was listed as fully protected under the California Endangered Species Act in 1974 (California Code of Regulations Title 14, Section 670.5; CDFG 2006) under California Code section 5515(a)(3)(b)(4). Fully protected species may not be taken or possessed at any time, except for scientific research or recovery efforts. The California Environmental Quality Act (CEQA) requires review of any project that is undertaken, funded, or permitted by the State or a local governmental agency. If significant effects to a listed species are identified, the lead agency has the option of requiring mitigation through changes in the project or to decide that overriding considerations make mitigation infeasible (CEQA section 21002). Protection of listed species through CEQA is, therefore, dependent upon the discretion of the lead agency involved. Lost River sucker may also receive benefits from the Lake and Streambed Alteration Program in California (California Fish and Game Code sections 1600-1616). This program provides a permitting process to reduce impacts to fish and wildlife from projects affecting important water resources of the State, including lakes, streams, and rivers. This program also recognizes the importance of riparian habitats to sustaining California's fish and wildlife resources, including state listed species, and helps prevent the loss and degradation of such habitats. The California North Coast Regional Water Quality Control Board, established in accordance with the Porter-Cologne Water Quality Control Act of California, has jurisdiction over water-bodies in portions of the Lost River sub-basin concerning impacts to water quality.

Lost River sucker were listed in 1991 as endangered under the Oregon Endangered Species Act of 1987 (Oregon ESA), as amended. The Oregon ESA prohibits the take (to kill, take possession of, or control) of Lost River Sucker (Oregon Administrative Rules 635-100-001 through 0180). It requires State agencies to consult with the Oregon Department of Fish and Wildlife (ODFW) if their actions on State land would violate the survival guidelines developed for a listed species. ODFW can recommend reasonable and prudent alternatives that are consistent with the survival guidelines. Under Oregon Revised Statutes (ORS 196.795-990) most actions that will remove or add materials to wetlands and waterways within the state must be permitted by the Oregon Department of State Lands and are required to mitigate for any impacts to state waters (ODSL 2011). Prior to listing as endangered, the Lost River sucker was regulated as a game species by the Oregon Department of Fish and Wildlife (Markle and Cooperman 2002); this would presumably resume upon recovery of the species.

Regulation of the quantity of water available in sucker habitats primarily involves the exercise of surface water rights for agriculture in both Oregon and California. The quantity of water

available in sucker habitat is dependent on climatic patterns and its affect upon stream-flow and groundwater inputs, which are influenced by human uses of water, some of which are subject to state regulation. Water rights claims by agriculture and other users in the Upper Klamath Lake sub-basin were under adjudication by the Oregon Department of Water Resources since 1975. The State of Oregon released its final order on the process on March 7, 2013. This order maintained that The Klamath Tribes and the United States (through the Department of the Interior) held several senior water rights in the upper Klamath Basin. These rights are senior, dated time in memorial, and must remain instream to uphold tribal treaty rights to fish in these areas. Calls for water by The Klamath Tribes on junior water users (as occurred in 2013) will presumably benefit the Lost River suckers by increasing water levels in Upper Klamath Lake and base flows in its tributaries. However, in July 2013, congressional delegates for Oregon convened a task force to explore a possible agreement between The Klamath Tribes and junior water users along the tributaries above Upper Klamath Lake. These negotiations are related to implementation of the Klamath Basin Restoration Agreement. They could result in substantial ecosystem improvements that would provide direct benefits to suckers inhabiting these tributaries. However, it is unclear at this time whether the task force will indeed produce a settlement that impacts the water regulation of the upper Klamath Basin.

The State of Oregon, through the Groundwater Act of 1955, regulates groundwater use through groundwater removal permits (Oregon Revised Statutes Sections 537.505 to 537.795 and 537.992). Most California groundwater is unregulated, and the State has no comprehensive groundwater permit process to regulate ground water withdrawal (California State Water Code Section 1200).

In summary, the Endangered Species Act is the primary Federal law that provides protection for this species since its listing as endangered in 1988. Other Federal and State regulatory mechanisms provide protections for the species based on current management direction, but do not guarantee protection for the species absent its status under the Act, with the exception of the Endangered Species Acts for each state. In general, these regulatory mechanisms provide protections to the species by restricting take (state Endangered Species Acts), by requiring review of actions that may impact the species (CEQA and NEPA), and by providing broad-scale improvements to habitat (Clean Water Act) or other means that affect habitat (such as water regulations). Nevertheless, we continue to believe that other laws and regulations have limited ability to protect the species in absence of the Endangered Species Act.

## **FACTOR E: Other Natural or Manmade Factors Affecting Its Continued Existence**

### Entrainment

Movement of fish into irrigation systems through unscreened diversions was identified as a threat to the suckers at the time of listing (USFWS 1988b). At that time thousands of suckers, including some adults, were entrained into the A-Canal, the largest diversion in the upper basin located near the Link River Dam. Although some of these fish were salvaged, many likely died (National Research Council 2004). The impact of entrainment into the irrigation system of the Klamath Project was reduced by construction of screening facilities over the A-Canal; although larvae are still at risk. Under the present design, fish screened from entering the A-Canal are

returned via pipeline to Upper Klamath Lake at a point that is near the river gates of the Link River Dam (Marine and Gorman 2005). Further investigations are needed to determine the overall effects and stress on transferred fish and if fish expelled through the pipeline remain in Upper Klamath Lake or are subsequently entrained by flows through the Link River Dam (USFWS 2007a, b).

Substantial entrainment occurs at the river gates of the Link River Dam (Marine and Lappe 2009). Currently these gates have no structures to prevent drawing fish downstream, but the East Side and West Side hydroelectric diversion facilities (operated by PacifiCorp) are currently shutdown between July 15 and November 15 to reduce entrainment when vulnerable life stages of listed suckers are present. During the late summer of 2006, over 3,500 age-0 juvenile suckers were collected in the Link River just below the dam with intermittent sampling of a fraction of the channel (Tyler 2007). The Committee on Endangered and Threatened Fishes in the Klamath River Basin of the National Research Council recommended screening to prevent downstream losses at Link River Dam (National Research Council 2004). Gutermuth *et al.* (2000) also documented tens of thousands of young suckers entrained at the PacifiCorp hydropower canals and turbines associated with the Link River Dam. Nonetheless, further research is required to better quantify the threats these structures pose to recovery.

Until recently, most suckers that pass through the gates at Link River Dam, or that survive passage through the hydroelectric facilities, were believed to be entirely lost from the breeding population. It was assumed that these fish either die in poor summer water quality conditions in Keno Reservoir, or pass further downstream into reservoirs along the Klamath River, from which upstream passage is blocked. However, recent surveys by the Bureau of Reclamation have detected a relatively small population residing in Lake Ewauna (see Distribution Section) indicating that some percentage of suckers do persist following passage through the Link River Dam gates or the hydroelectric facilities. A new fish ladder was also constructed at Link River Dam in 2004 through which adult suckers have been documented (using PIT tag readers) moving upstream through Link River. As of 2008, only seven individuals had been documented as passing through the ladder (Korson et al. 2008); however, at least 20 individuals were documented in the ladder during 2010 and 2011 (T. Tyler, pers. comm. 2010). Since only PIT-tagged individuals that swim close enough to the PIT-readers' antennae (generally within a couple of feet) can be detected and the numbers of tagged suckers in Lake Ewauna are still extremely low, these values are probably underestimates of the total number using the ladder.

There are also significant unscreened diversion structures that divert water from Lake Ewauna, including the Lost River Diver Channel and Ady Canal, but we aren't aware of any data indicating the amounts of entrainment through these structures. In addition to major diversion points, several hundred small, typically unscreened diversions in tributary streams and rivers and the lakes proper may also affect Lost River sucker. In 2001, the Bureau of Reclamation reported 193 diversions within the Klamath Project that were "directly connected to endangered sucker habitat below Upper Klamath Lake," with only three of these diversions equipped with fish screens (Bureau of Reclamation 2001: 2). The Bureau also noted there are at least 24 large diversions outside of the Klamath Project Service area that have the potential of entraining suckers. The influence on sucker abundance and recovery of these diversions is unknown.

Since listing, private landowners, the Oregon Department of Fish and Wildlife, Reclamation, the Natural Resource Conservation Service, the Service, and others have built or funded construction of many new fish screens in the upper basin (Table 2). As a result, the threat of entrainment (loss of fish as result of being drawn into water management structures) is now lower than at the time of listing. Recently-installed fish screens in the upper basin include the A-Canal (2003), Agency Lake Ranch (2002), Clear Lake Reservoir (2003), Miller Island (2003), Wood River Ranch (2004), and Geary Canal (2009). Various State and Federal screening and passage programs, coordinated in the upper basin through a working group led by Bureau of Reclamation, are addressing the need for additional screening and passage for suckers. The Bureau of Reclamation surveyed water diversion structures throughout the Klamath Project service area (which excluded non-project users) between 1997 and 2000. This survey documented approximately 200 diversions that were directly connected to Lost River sucker habitat. A few of these are very large and likely impact the species, but many are small and have minimal impacts. We do not believe that most of the small diversions pose a serious threat to Lost River sucker populations because these smaller diversions typically draw water from the streams and rivers, but most suckers are in the lakes when the diversions are in operation. Also, small diversions draw relatively moderate currents which are likely to only entrain larvae, which are produced in large numbers, naturally experience very high rates of mortality, and would not be benefitted by most screens which typically only effectively exclude fish that are larger than 30 mm in length

**Table 2 A summary of recent major entrainment reduction projects benefitting Lost River sucker populations. Many of these projects were cooperative efforts of many state and federal agencies, non-profit organizations, and private landowners.**

Project	Year Completed	Potential Benefits
A-canal Screen	2002	Retain more larvae and juveniles in Upper Klamath Lake by limiting entrainment into the canal
Clear Lake Dam Screen	2003	Retain more larvae, juveniles, and adults in Clear Lake Reservoir by limiting entrainment into the canal
Modoc Irr. Dis. Williamson River Div. Screen	2007	Reduce larval mortality due to entrainment
Geary Canal Screen	2009	Retain more larvae and juveniles in Upper Klamath Lake by limiting entrainment into the canal

## Climate

Climate variability, such as fluctuations between wet and dry periods, is part of natural processes; however, climatic models suggest that much of the recent trends in climate is driven by anthropogenic causes (Barnett et al. 2008). Since the 1950's, western North America generally has exhibited trends toward less snowfall, earlier snowmelt, and earlier peak spring runoff, much of which cannot be attributed to natural fluctuations (Hamlet et al. 2005, Stewart et al. 2005, Knowles et al. 2006). Furthermore, models indicate that these trends are likely to continue into the future (Barnett et al. 2008). More specifically, a suite of climate models predict

that over the next 100 years the mean flow of the Sprague River will increase during winter months but decrease during the spawning period (Markstrom et al. 2012, Risley et al. 2012), a pattern which is likely to be exhibited throughout the upper Klamath Basin.

It is difficult to accurately predict how such climatic changes will affect the Lost River sucker. These species are adapted to weather periodic droughts (Dicken and Dicken 1985, Negrini 2002), but given the current reduced state of the species, they may be negatively impacted if there is an increase in the intensity or frequency of droughts or a substantial shift in the timing of snowmelt and runoff. Likewise, detrimental changes in refugia availability or community composition may also accompany climate change (Dahm et al. 2003, Magoulick and Kobza 2003).

### III. RECOVERY CRITERIA

Recovery plans provide guidance to the Service, States, and other partners and interested parties on ways to minimize threats to listed species, and on criteria that may be used to determine when recovery goals are achieved. There are many paths to accomplishing the recovery of a species and recovery may be achieved without fully meeting all recovery plan criteria. For example, one or more criteria may have been exceeded while other criteria may not have been accomplished. In that instance, we may determine that, overall, the threats have been minimized sufficiently, and the species is robust enough, to downlist or delist the species. In other cases, new recovery approaches and/or opportunities unknown at the time the recovery plan was finalized may be more appropriate ways to achieve recovery. Likewise, new information may change the extent that criteria need to be met for recognizing recovery of the species. Overall, recovery is a dynamic process requiring adaptive management, and assessing a species' degree of recovery is likewise an adaptive process that may, or may not, fully follow the guidance provided in a recovery plan. We focus our evaluation of species status in this 5-year review on progress that has been made toward recovery since the species was listed (or since the most recent 5-year review) by eliminating or reducing the threats discussed in the five-factor analysis. In that context, progress towards fulfilling recovery criteria serves to indicate the extent to which threat factors have been reduced or eliminated.

A recovery plan for the Lost River sucker and the shortnose sucker was finalized on March 17, 1993 (USFWS 1993). A combined plan was prepared for these species due to their similar biology, distribution, and threats, but no criteria for downlisting or delisting were provided in the first version of the Recovery Plan. A substantial amount of additional information has accumulated during the interim and the plan was revised to incorporate this new information into the recovery program as well as recovery criteria. The final Revised Recovery Plan for the Lost River sucker (*Deltistes luxatus*) and Shortnose sucker (*Chasmistes brevirostris*) (USFWS 2013), was released in April 2013. With few exceptions, none of the criteria are close to being met at this time, primarily because the criteria will be achieved through the future implementation of multiple actions just identified in the now-published plan. The criteria for assessing recovery of Lost River sucker from this plan are as follows, with associated actions that are currently being implemented:

**Factor A – Downlisting Criteria**

- A.1 Current spawning and rearing habitat is maintained and improved access ensures annual use. Protections provided under the Act are helping to maintain spawning and rearing habitat that exists at this time, but no actions have been implemented yet to improve annual access to these areas.
- A.2 A range-wide Spawning and Rearing Enhancement Plan has been developed and implemented. This plan shall identify and prioritize areas of potential spawning and rearing habitat for enhancement and/or restoration, including areas which are degraded or unavailable due to lack of connectivity or passage. Development of this plan has not been initiated yet because it was only recently identified in the revised Recovery Plan (April 2013).
- A.3 Connectivity and access is assured to habitats that provide refuge to suckers to avoid poor water quality (particularly Pelican Bay) during the months of July, August, and September – Upper Klamath Lake Recovery Unit. Recent data indicates that depths required for access into Pelican Bay may be sufficient for Lost River sucker access. However, further evaluation and checks of the new data need to be completed to ensure accuracy.
- A.4 Restore natural vegetated wetland areas, including in-stream, wetland and riparian areas around the mouth of Willow Creek where it meets Clear Lake Reservoir – Clear Lake Reservoir Management Unit. There are no actions being implemented yet under this criterion.

**Factor C – Downlisting Criteria**

- C.1 Newly identified or clarified effects of predation and disease are minimized through implementation of recommendations from ongoing scientific research which clarifies the interaction of Lost River sucker with predators and pathogens. There are no actions being implemented yet under this criterion.

**Factor E – Downlisting Criteria**

- E.1 An Entrainment Reduction Plan has been developed and implemented. This plan shall identify and prioritize screening of diversions throughout upper Klamath Basin, including the Klamath Project, and propose strategies for efficient reduction of entrainment. Development of this plan has not been initiated yet because it was only recently identified in the revised Recovery Plan (April 2013).
- E.2 Establishment of two additional recurring and successful spring-spawning populations in the Upper Klamath Lake-Spring Management Unit. There are no actions being implemented yet under this criterion.
- E.3 Development and implementation of a plan to assess, monitor, and improve juvenile and sub-adult vital rates and demography, including threats and negative impact reduction. This plan shall also designate specific demographic or vital rate targets, and strategies for achieving these targets, important for downlisting and delisting. Development of this plan has not been initiated yet because it was only recently identified in the revised Recovery Plan (April 2013).
- E.4 The effects of detrimental water quality have been minimized through implementation of recommendations from ongoing scientific research which clarifies the relationship of these factors with sucker mortality – Upper Klamath Lake Recovery Unit. This criterion

is not close to being met because it involves a complex mixture of many factors, such as landscape level nutrient dynamics and species life history and ecology, but the USFWS and the Bureau of Reclamation, as well as others, are conducting research to better clarify the relationship between water quality and Lost River sucker mortality.

#### **Factor B – Delisting Criteria**

- B.1 The States of Oregon and California and the Klamath Tribes, collaboratively or separately, should prepare and finalize population management plan(s) for the species. Development of this plan has not been initiated yet because it was only recently identified in the revised Recovery Plan (April 2013).

#### **Factor E – Delisting Criteria**

- E.5 After 25 years, the average annual rate of population change is greater than one and the number of spawning individuals is greater than what was present in the baseline years for the Upper Klamath Lake River and Upper Klamath Lake Spring Management Units. [See Appendix II of the draft revised recovery plan for descriptions and estimation procedures of these measures.] Twenty-five years equates to approximately two average adult life spans for Lost River sucker, and will enable assessment of the populations' response to cyclical threats, such as periodic die-offs and drought. 2002 will serve as the baseline years for Lost River sucker, since this is the first year in which estimates of this type are statistically valid. This criterion can be met at the earliest in 2027, based on the 25-year timeframe built into the criterion. In addition, the present trajectory of the species is in a direction not consistent with meeting this criterion.

### **IV. SYNTHESIS**

Historically, Lost River suckers were extremely abundant throughout the Klamath Basin. However, as habitats were made unavailable or unsuitable through destruction, obstruction, modification, and introduction of non-native species, the Lost River sucker declined to relatively low numbers. The 2007 5-year status review for the Lost River sucker recommended that the species be downlisted to threatened status based on 1) data indicating higher numbers of Lost River sucker in Upper Klamath Lake than estimated at the time of listing, and 2) indications that the population in Clear Lake Reservoir was experiencing recruitment. The 2007 status review also discussed the detection of individuals in Tule Lake and the benefits to the species from restoration activities, but acknowledged that significant threats still remained. New data indicate that the reasons provided in the 2007 5-year review for recommending downlisting the Lost River sucker to threatened are no longer supported.

First, although higher numbers of Lost River suckers certainly do exist in Upper Klamath Lake than thought at the time of the final listing rule, the population is consistently declining because of a lack of recruitment to the adult population (Hewitt et al. 2012). The Upper Klamath Lake spring-spawning population has declined by approximately 45 percent since 2002.

Secondly, in 2007, approximately 35 percent of all individuals captured in Clear Lake Reservoir were less than 400 mm, a size indicative of relatively young adults, indicating that recruitment to the adult population was occurring or about to occur. However, as of 2011, only 25 percent of

this group was still being detected in the spawning runs suggesting mortality rates for this young adult group of nearly 75 percent. For this species, annual adult mortality rates greater than 15 – 20 percent can significantly decrease population stability and viability. The data now indicate that the adult population continues to age with few new individuals surviving to reproductive age to offset natural mortality.

As discussed in the previous 5-year review, Lost River suckers do occur in sump 1A of Tule Lake, but larval production is minimal, if any. Although this population is valuable to the species as an auxiliary population, it is not self-sustaining and does not currently contribute to recovery of the species. Tule Lake is believed to be a sink population (meaning a population without enough production to be self-sustaining but is maintained by immigrants from other, productive populations). Given this, it provides backup only so long as productive populations sustain it.

Between 2004 and 2012 some substantial threats were reduced through construction of the A-canal screen and Link River Dam ladder, restoration of the Williamson River Delta, and removal of the Chiloquin Dam. Nevertheless, significant threats to the Lost River sucker remain, including extremely poor water quality in Upper Klamath Lake and other areas, fluctuations in available water quantity and drought, fragmentation of populations, entrainment, non-native species, and climate change. These threats increase mortality rates, reduce reproduction, and inhibit natural metapopulation dynamics. Although, the individual impacts of each of these threats on the status of the species are poorly understood, the extinction of this species remains a credible possibility. This is especially apparent given that only two populations exhibit any appreciable larval production, but neither of these experiences sufficient recruitment to the adult population to replace individuals lost at normal mortality rates. The largest and most important population, Upper Klamath Lake, has declined by approximately 45 percent since 2002. This is a general estimate given that there are slight differences between males and females, and between subpopulations in the lake. The population in Clear Lake Reservoir also appears to be ageing without new individuals joining the adult population. All other areas support extremely small numbers of individuals due to unsuitable habitat and/or a complete lack of larval production.

Because of the new data and the continued threats to the species, the 2007 5-year review recommendation to downlist the Lost River sucker to threatened is no longer supported. We conclude that the Lost River sucker is still in danger of extinction throughout its entire range and should remain classified as endangered.

## V. RESULTS

### Recommended Listing Action:

- ☐ Downlist to Threatened
- ☐ Uplist to Endangered
- ☐ Delist (indicate reason for delisting according to 50 CFR 424.11):
  - ☐ *Extinction*
  - ☐ *Recovery*
  - ☐ *Original data for classification in error*
- ☒ No Change

### New Recovery Priority Number and Brief Rationale:

The Lost River sucker recovery number should remain “4C.” This number indicates a monotypic species that has a high degree of threats and a low recovery potential. The “C” indicates that the species is in conflict with construction or other development projects or other forms of economic activity.

## VI. RECOMMENDATIONS FOR ACTIONS OVER THE NEXT 5 YEARS

### Establishment of a Recovery Implementation Team

The revised recovery plan for the Lost River sucker (USFWS 2013) identifies several actions that will promote recovery of this species. Among these is the establishment of a Recovery Implementation Team to coordinate and assess implementation of the plan. This is a very important step to ensure success of the plan.

### Improving Recruitment

The most critical need for this species is to restore natural rates of recruitment to Upper Klamath Lake and Clear Lake Reservoir populations. Research is needed to clarify how adverse water quality (including algal toxins), entrainment, and habitat availability affect this lack of recruitment.

### Auxiliary Populations

Given that Lost River sucker are steadily declining in the only two populations with any appreciable reproduction, the Revised Recovery Plan (Revised Recovery Plan; USFWS 2013), calls for the establishment of auxiliary populations within the natural range of the species to guard against short-term extinction risks. This includes the reestablishment of spawning populations in the Upper Klamath Lake tributaries and springs. The Revised Recovery Plan (Service 2013) also stresses the importance of conserving the Tule Lake population for redundancy within the Lost River system. The plan also identifies several priority actions that include investigating the potential of restoring spawning habitat for this population.

**U.S. FISH AND WILDLIFE SERVICE  
5-YEAR REVIEW**

**Lost River sucker (*Deltistes luxatus*)**

**Current Classification:** Endangered

**Recommendation Resulting from the 5-Year Review:**

☐ Downlist to Threatened  
☐ Uplist to Endangered  
☐ Delist  
☒ No change needed

**Review Conducted By:** Josh Rasmussen, Klamath Falls Fish and Wildlife Office, Klamath Falls, Oregon

**Date Submitted to Region 8:** August 06, 2013

**FIELD OFFICE APPROVAL:**

**Lead Field Supervisor, U.S. Fish and Wildlife Service**

Approve  Date 8/1/2013

**REGIONAL OFFICE APPROVAL:**

**Lead Assistant Regional Director, Ecological Services, U.S. Fish and Wildlife Service,  
Region 8  
Acting**

Approve  Date 8/22/13

**Appendix 1 Documented or suspected Lost River sucker spawning sites in the Williamson River system.**

<b>Site Name</b>	<b>River and River Mile</b>	<b>Reference</b>
Beatty Gap	Sprague 70-75	Ellsworth et al. (2007)
Chiloquin High School	Sprague 0.8	Bienz and Ziller (1987); Coleman et al. (1988); Buettner and Scoppettone (1990)
Chiloquin Narrows	Sprague 6-8	Ellsworth et al. (2007)
Hwy 97 Bridge	Williamson 7.3	Bienz and Ziller (1987); Coleman et al. (1988); Buettner and Scoppettone (1990)
Kircher's Bridge	Sprague 0.7	Bienz and Ziller (1987); Coleman et al. (1988); Buettner and Scoppettone (1990)
Mobile Home	Sprague 4.8	Coleman et al. (1988); Buettner and Scoppettone (1990)
Painted Rock/ Chiloquin Dam	Sprague 0.9	Bienz and Ziller (1987); Coleman et al. (1988); Buettner and Scoppettone (1990)
River's Bend	Sprague 5.2	Coleman et al. (1988); Buettner and Scoppettone (1990)
Side Channel	Williamson 11.0	Coleman et al. (1989); Buettner and Scoppettone (1990)
Sportsman's Park	Williamson 10.6	Bienz and Ziller (1987), Coleman et al. (1988); Buettner and Scoppettone (1990)
Unnamed	Williamson 6.3	Bienz and Ziller (1987)
Unnamed	Williamson 9.6-10.6	Bienz and Ziller (1987)
Waterwheel Park	Williamson 7.1	Bienz and Ziller (1987); Coleman et al. (1988); Buettner and Scoppettone (1990)

## Appendix 2 Historical and current occurrences of Lost River sucker.

Area	Occurrence	Reference
<i>Upper Klamath Lake and Shoreline Springs</i>		
Upper Klamath Lake	Currently Present	Cope (1879); numerous reports thereafter
Barkley Spring	Extirpated by the late 1970s but little evidence of when or how big the population was	Perkins et al. (2000a)
Boulder Spring	Currently Present	Shively et al. (2000b); Barry et al. (2007); Janney et al. (2009)
Cinder Flats	Currently Present	Shively et al. 2000; Barry et al., 2007; Janney et al. 2009
Harriman Spring	Extirpated, last seen in 1975	Andreasen (1975)
Odessa Spring	Extirpated but little evidence of when or how big the population was	Golden (1969)
Ouxy Spring	Currently Present	Andreasen (1975); Shively et al. (2000a); Janney et al. (2009)
Sliver Building Spring	Currently Present	Andreasen (1975); Shively et al. (2000a); Janney et al. (2009)
Sucker Springs	Currently Present	Andreasen (1975); Shively et al. (2000a); Janney et al. (2009)
<i>Upper Klamath Lake Tributaries</i>		
Crooked Creek	Present at head of creek in 1974; unidentified larvae and adult suckers seen in 1991	Andreasen (1975); Stine (1982); Logan and Markle (1993)
Crystal and Recreation Creeks		Mulligan et al. (2009)

Area	Occurrence	Reference
Crystal Creek	Small run reported by Golden (1969), now extirpated but little evidence of when or how big the population was	Golden (1969); Mulligan et al. (2009)
Fort Creek	Unidentified suckers observed ca. 1990	Logan and Markle (1993)
Fourmile Creek	Small run reported, now extirpated but little evidence of when or how big the population was	Golden (1969)
Lower Fourmile (near Pelican Bay)		Mulligan et al. (2009)
Lower Odessa Creek		Mulligan et al. (2009)
lower Sycan River	Single radio-tagged individual was briefly detected.	Ellsworth et al. (2007)
Lower Williamson River	Currently Present	Golden (1969); many recent reports by USGS but especially Ellsworth et al. (2007)
Malone Springs		Mulligan et al. (2009)
Sevenmile Creek	Small run reported, now extirpated	Golden (1969)
Sprague River	Present upstream to Beatty Gap ~ RKM 75	Golden (1969); many recent reports by USGS, but especially Ellsworth et al. (2007)
Upper Williamson River	Not detected	
Wood River	One adult present in lower river in 1996, small number of adults present in Agency Lake near mouth in 1996,1999, and 2000	BOR (2001)

Area	Occurrence	Reference
<b><i>Upper Klamath River</i></b>		
Copco Reservoirs	Currently Present	Desjardins and Markle (2000)
Iron Gate Reservoir	Currently Present	Desjardins and Markle (2000)
J.C. Boyle Reservoir	Currently Present	Desjardins and Markle (2000)
Keno Reservoir/Lake Ewauna	Currently Present	Kyger and Wilkens (2010)
Link River	Historically significant runs, runs very small or extirpated	Golden (1969)
Lower Klamath Lake	Presumed Extirpated	Coot (1965)
Sheepy Creek	Presumed Extirpated	Coot (1965)
<b><i>Lost River Sub-basin</i></b>		
East Fork Lost River below Willow Valley Reservoir	Undetected	Shively et al. (2000b)
Lost River - Anderson Rose Dam to Tule Lake	Currently Present	Buettner and Scoppettone 1991; Hodge and Buettner (2009a)
Lost River - Clear Lake Reservoir to Malone Reservoir	Undetected	Koch et al. (1975); Buettner and Scoppettone (1991); Shively et al. (2000b); Sutton and Morris (2005)
Lost River - Harpold Dam to Lost River Diversion Dam	Currently Present	Shively et al. (2000b)
Lost River - Lost River Diversion Dam to Anderson Rose Dam	Undetected	Koch and Contreas (1973); Shively et al. (2000b)
Lost River - Miller Creek Confluence to Harpold Dam	Present in 1973	Koch and Contreas (1973); Shively et al. (2000b)
Malone Dam to Miller Creek confluence	Undetected	Shively et al. (2000b)

Area	Occurrence	Reference
Tule Lake	Currently Present	Scoppettone et al. (1995); Hodge and Buettner (2009); Courter et al. (2010)
<i>Clear Lake Reservoir and Tributaries</i>		
Clear Lake Reservoir	Currently Present	Buettner and Scoppettone (1991); Barry et al. (2009)
Antelope Creek (lower reach)	Undetected	Koch et al. (1975); Buettner and Scoppettone (1991)
Avanzino Reservoir	Last observed in 1995	Perkins and Scoppettone (1996)
Bagley Creek	Undetected	Coot (1965); Sonnevil (1972); Buettner and Scoppettone (1991); Perkins and Scoppettone (1996)
Bayley Tank Reservoir	Undetected	Koch et al. (1975); Buettner and Scoppettone (1991); Perkins and Scoppettone (1996)
Boles Meadow Reservoir	Undetected	Koch et al. (1975); Buettner and Scoppettone (1991) ; Perkins and Scoppettone (1996)
Fletcher Creek	Last observed in 1990	Sonnevil (1972); Buettner and Scoppettone (1991); Perkins and Scoppettone (1996)
Lower Fourmile Reservoir	Undetected	Buettner and Scoppettone (1991)
Mowitz Creek	Undetected	Perkins and Scoppettone (1996)
Telephone Flat Reservoir	Undetected	Buettner and Scoppettone (1991); Perkins and Scoppettone (1996)

Area	Occurrence	Reference
Weed Valley Reservoir	Undetected	Buettner and Scoppettone (1991)
Wildhorse Reservoir	Undetected	Buettner and Scoppettone (1991); Perkins and Scoppettone (1996)
Willow Creek	Currently Present	Buettner and Scoppettone (1991); Barry et al. (2009)
<b><i>Gerber Reservoir and Tributaries</i></b>		
Gerber Reservoir and drainage	Undetected throughout	Buettner and Scoppettone (1991)
